Table 3
Overlap to CNEs provided by the CONDOR [1] database.
We performed BLAST searches against four sets of vertebrate CNEs given by the CONDOR project. We list the number of recovered UCRs that have a significant BLAST hit (E-value $<=1 \mathrm{e}-3$ ) and the amount of hits with $100 \%$ sequence identity. CONDOR CNEs only require $>65 \%$ sequence identity over at least 40 nt yielding a plenty of sequences conserved between fugu and other mammals. However, we notice 810 UCRs conserved between the genomes of fugu and human (see Figure 3 of the main paper) but only 612 resp. 491 UCRs have sequence similarity with fugu resp. human CONDOR CNEs.

| species | \# CONDOR CNEs | recovered UCRs | $100 \%$ identity |
| :--- | :---: | :---: | :---: |
| fugu | 6794 | 612 | 597 |
| human | 6771 | 491 | 83 |
| mouse | 6489 | 454 | 87 |
| rat | 5601 | 402 | 75 |
| all | - | 411 | 396 |

Fig. 1. A simple example of consistency checks validating three global alignments A, B, C.
The validation process sets up the four graphs $G_{S}, G_{C}, G_{I}$ and $G_{F}$.
$G_{S}$ : An edge between two vertices (local alignments) is inserted if they have a distance $\leq 30 n t$ to find all combinations of consistent global alignments.
$G_{C}$ : Edges occur between consistent pairs of local alignments.
$G_{I}$ : Edges occur between inconsistent pairs of local alignments.
$G_{F}$ : An edge is inserted between $x$ and $y$ if there exists at least one path from $x$ to $y$ in $G_{C}$ which does not contain vertices connected in $G_{I}$
Cliques in $G_{F}$ are local alignments which can be combined to a consistent global alignment. In the example there is one single trivial clique, thus A and C are consistent and can be combined.

Table 4
Sensitivity analysis of the gammaproteobacteria RNAz screen, part A.

| Flanking regions | NcDNAlign, default Blast |  | NcDNAlign, |  | TBA |

| Noncode | 7 | 9 | 16 | 16 | 17 |
| ncRNAdb | 10 | 9 | 9 | 28 | 30 |

a Based on known RNAs detected by RNAz; Obviously, only those RNAs which are
present in the RNAz input alignments are detectable.

Fig. 2. Exemplary illustration of the alignment beautification procedure.
Consider an initial six-way alignment. Taking into account to minimize the number of sequence losses, the two most restricting sequences of the alignment length are determined. Herein, the optimization algorithm decides to drop sequence four because there are simply more sequences involved (blue dots) at the right than at the left side $(5>4)$ of the minimal overlapping region (red). As a consequence, the length of the minimal overlapping region increases. Repeating the beautification could enlarge the overlap again until a certain cutoff-length is reached or the alignment contains no more dispensable sequences.
